TITLE: Technology of manufacture and properties of electric lead-ins of corundum microlite, operating in corrosive media at high temperatures and pressures

SOURCE: Teplofizika vysokikh temperatur, v. 3, no. 2, 1965  
260-265

ABSTRACT: The authors describe electric lead-ins into a region containing a corrosive substance at high temperature and pressure. The bushing insulators are made from corundum microlite and platinum-rhodium wire, and are sintered at 1750C. The compositions and the manufacturing steps are described in detail. The lead-ins were used to determine the electric conductivity of various substances (NaCl, KCl, Na<sub>2</sub>SiO<sub>3</sub> and others) in water and in steam at 250 -- 500C and at

TITLE: Construction properties of corundum microlite at high  
temperatures

SOURCE: Teplofizika vysokikh temperatur, v. 4, no. 2, 1966, 202-206

TOPIC TAGS: high temperature alloy, corundum refractory

ABSTRACT: The article presents a correlation of experimental and literature data on the mechanical, physico-chemical, and thermo-physical properties of corundum microlite at room temperature and at high temperatures (up to 1200°C). The corundum microlite used had the following composition: 99.4-99.5%  $\text{Al}_2\text{O}_3$ ; 0.5-0.6% MgO; 0.03-0.05%  $\text{Fe}_2\text{O}_3$ . The samples were annealed in a batch type flame furnace with prolonged heating for 16 hours at 400°, and then for 12 hours at 1750°. The following properties of the samples were determined: water absorption, specific weight, porosity, hardness, coefficient of linear

thermal expansion, specific electric resistance, the strength limit for shock bending, fracture, and compression at room temperature, thermal stability, electric strength, refractory properties, deformation temperature, and shrinkage. The experimental results are shown in a table and figures. There is also a photo at 90 magnifications of the microstructure of the corundum microlite. It was found that the material has attractive properties for use as a construction material in machine construction, in the electrical industry, and for high temperature units which operate in aggressive media. AUTHOR: Vasil'yeva, G. Ya.

TITLE: Some results of studying tremors of stars using their tracks

PERIODICAL: Referativnyy zhurnal. Astronomiya i Geodeziya, no. 9, 1961, 31-32,  
abstract 9A246 ("Tr. Soveshchaniya po issled. mertsaniya zvezd",  
1958, Moscow-Leningrad, AN SSSR, 1959, 165-173. Discuss., 181-182)TEXT: Turbulence was studied in detail by means of plotting autocorrelation functions for 13 stellar tracks. Observations were conducted at Anapa with an A3T-7 (AZT-7) telescope ( $f = 10$  m,  $D = 200$  mm). Each track was measured at 600 points separated by  $50 \text{ m} \mu$ . Calculations were carried out on an 3B-80-3 (EV 80-3) electronic computer at the Computing Center, AS USSR. The results of this work confirm the conjecture on the existence of a periodic non-random component in tremors. The energy of non-random component amounts to 10-20% of total energy of the oscillation process, and this ratio does not depend either on azimuth or on zenith distance of the star. TITLE: Desulfurization of petroleum and petroleum products by oxidation.  
2. Desulfurization of benzene and kerosene fractions by atmospheric oxygen  
oxidation in an alkali medium

SOURCE: AN SSSR. Bashkir'skiy filial. Khimiya seraorganicheskikh soyedineniy,  
soderzhashchikhsya v neftyakh i nefteproduktakh, v. 7, 1964, 192-195

TOPIC TAGS: desulfurization, petroleum, benzene, kerosene, fraction, oxidation,  
catalyst, sodium hydroxide, alkali

ABSTRACT: Experiments were carried out to determine the optimum conditions for  
desulfurizing benzene and kerosene fractions from the Ural-Volga oil fields by  
oxidizing them in atmospheric oxygen and a water-alkali medium at high pressures  
and temperatures. The experiments were conducted in laboratory bubbling columns  
with perforated bottom vertical tubes. The first desulfurization was done with  
platforming type benzene 80-122°C fractions. A great improvement was noticed in  
the desulfurization efficiency when using an alkali catalyst. The optimum

Card 1/2

L 42106-65

ACCESSION NR: AT5008632

conditions were: temperature 60°C, air flow one liter/minute, NaOH concentration 3%, alkali to benzene ratio 1:2, pressure 10 atm, and test duration 10 minutes. The second specimen was of a 150-200°C benzene fraction. The optimum conditions were: temperature 130°C, air flow one liter/minute, alkali concentrate 3%, alkali-benzene ratio 1:1, pressure 10 atm, and test duration time 10 minutes. Similar conditions were found for the 200-300°C fraction specimen. Orig. art. has 4 tables.

TITLE: The problem of the oxidative desulfurization of the rectified fractions of sulfurous petroleums. Desulfurization of the rectified fractions of sulfurous petroleums by oxidation in an autoclave

CITED SOURCE: Tr. Leningr. tekhnol. in-ta im. Lensoveta, vyp. 63, 1964, 168-172

TOPIC TAGS: petroleum refining, desulfuration, oxidative desulfurization, sulfurous crude, organic sulfur, sulfur oxidation

TRANSLATION: These studies were carried out on high-sulfur crudes from Patos (Albania), on the > 200°C distillate of petroleum from Zol'nyy Ovrag, and on the 80-140, 140-200, 200-240 and 240-270°C fractions of the representative petroleum Vtoroy Baku from Romashkino. Oxidation was carried out with atmospheric O<sub>2</sub> in an alkaline medium under pressure; the temperature in the experiments fluctuated between 120 and 220°C, and the pressure, from 10 to 20 atmospheres. The results of these studies demonstrated the possibility of removing the S compounds from rectified petroleum fractions. The alkaline medium acts as

Line 1/2

L 43090-65  
ACCESSION NR: AR5006829

an inhibitor of the oxidation of the hydrocarbons in the fraction; at the same time, the S compounds of the fraction are bound by alkali after being transformed into the active form of quadrivalent and hexavalent S. The oxidation of the sulfoorganic compounds can be accelerated by the use of the catalyst  $CuCl_2 \cdot 2H_2O$ . Preliminary experiments, carried out with the 240-270°C kerosene fraction of Romashkino petroleum, showed that the degree of desulfurization is significantly increased by this process, even when the temperature is decreased to 120°C, while the physicochemical constants before and after the experiment are identical. However, oxidation in a rotating autoclave proceeds at an excessively slow speed due to the small reactive surface and the poor dispersion of the petroleum fraction in the aqueous solution of alkali. Translation from: Referativnyy zhurnal. Mashinostroyeniye, 1959, Nr 16, p 135 (USSR)

AUTHOR: Vasil'yeva, G.S.

TITLE: Nickel Plating in Fluoborate Electrolyte

PERIODICAL: Materialy po obmenu opytom i nauchn. dostizh. Vses. n.-i. in-t med. instrumentariya i oborud., 1958, Nr 4 (29), 82 - 87

ABSTRACT: Results of an investigation are given which was carried out with the aim of studying the possibilities of intensifying the process of nickel plating in a fluoborate electrolyte and, at the same time, of finding the methods to eliminate the tendency of this electrolyte to pitting. The method of preparing the electrolyte is described: 350 milliliter/l of concentrated HF are added to 215 grams/liter of  $H_3BO_3$ . The solution is decanted and freshly precipitated  $NiCO_3$  is introduced up to the saturation point. Then 15 grams/liter of nickel chloride are added, the solution is filtered and its pH is brought to 2.5 - 3.5 by introducing NaOH. Nickel plating is effected at a temperature of 50°C, with a current density of 4 - 4.5 amp/dm<sup>2</sup> and with an intensive air agitation. The tendency of the electrolyte to pitting is eliminated by an electrochemical dipping of the parts in a solution containing (in % by weight): 60 -  $H_3PO_4$ , 10 -  $H_2SO_4$ , 30 -  $H_2O$ , at a

Abstract : Study of the effect of preliminary treatment (mechanical and chemical), composition of electrolyte and conditions of electrolysis, on the porosity (P) of Ni-deposits. It was found that the better the mechanical treatment of the surface the less is the P. Use of electrolytic pickling in a solution having the composition (in % by weight): H<sub>2</sub>PO<sub>4</sub> 60, H<sub>2</sub>SO<sub>4</sub> 10 and H<sub>2</sub>O 30, or in a solution of H<sub>3</sub>PO<sub>4</sub>

(specific gravity 1.72) lowers the P. Increased acidity  
of the electrolyte and a lowering of the concentration of  
 $H_3BO_3$  below 10 g/liter increases the P. Passivation of  
the surface prior to nickel plating decreases, by 1.5-2  
times, the protective properties of the coating. P is  
increased on contamination of the electrolyte with Fe and  
dextrin. Increase of  $D_k$  to 2 a/dm<sup>2</sup> results in a dark,  
porous deposit. Other conditions of electrolysis have  
little effect on P.

TITLE: The Effect of Technological Factors on the Porosity of Electrically-positive Nickel (Vliyanie tekhnologicheskikh faktorov na porostost' elektricheskikh nikel'evykh osadkov)

PERIODICAL: Materialy po obmenu opytom i nauchn. dostizh. v med. prom-sti, 1957, Nr 3 (22), pp 31-42

ABSTRACT: The results of work to clarify the effect of the following elements on the porosity of Ni coatings (C) are presented: preparation of the surface of the parent metal before coating, electrolyte composition, working environment, contamination of electrolyte, passivation of the surface of the parent metal before coating. It is shown that preparation of the surface of the parent metal is one of the most decisive factors in producing compact electrolytic C. It is shown that electrochemical passivation increases the density and protective effect of the C for a given thickness. It is recommended that electrolytic passivation be performed with a bath consisting of 60% orthophosphoric acid, 10%  $H_2SO_4$ , and 30% water.

The Effect of Technological Factors (cont.)

and also phosphoric acid. The porosity of the C is not dependent upon the kind of Ni bath. However, porosity increases as the  $H_3BO_3$  concentration diminishes. The  $H_3BO_3$  content should not be less than 10 grams per liter. The acidity of the bath significantly affects the continuity and the protective properties of the C. The optimum acidity of the bath occurs when the pH is in the 4.5-5.5 interval. Variation in the  $D_k$  from 0.25 to 2.5 amp/dm<sup>2</sup> and in bath temperature from 20-70°C does not significantly affect the porosity of the C. An increase in the thickness of C diminishes its porosity. Stirring of the bath has no real effect upon the continuity of the C. Contamination of the bath by Fe or by dextrin induces an increase in the porosity of the C, its brittleness and surface brightness, and also surface pitting. Passivation of the surface of the parent metal before nickel-plating decreases the protective capacity of the C by 33-50 percent for a layer of given thickness.

TITLE: Effect of the penetration zone on convective heat and mass transfer in evaporative cooling

SOURCE: Inzhenerno-fizicheskiy zhurnal, v. 9, no. 3, 1965, 405-408

TOPIC TAGS: thermodynamics, heat transfer, mass transfer, evaporative cooling

ABSTRACT: The experiment was carried out in an aerodynamic assembly with a rectangular cross section area of 16 square meters and at a constant air velocity of 5 meters/sec. The dynamic pressure was measured with a Pitot-Prandtl tube. The relative moisture content of the air was maintained constant by an automatic system. The working materials were quartz sand with particle sizes of 0.8, 0.4, and 0.6 mm. The amount of water introduced was measured with an accuracy of 0.1%. The dry layers were investigated in thicknesses of 0, 2, 3, 4, 5, 6 and 8 mm. In evaluating the strong effect of the sinking down of the evaporation surface on the heat and mass transfer coefficients, special attention was paid to maintaining the thickness of the dry layer over the whole surface of the body.

Figures show the distribution of the profile of the temperature gradient over the depth of the layer of sand. Results showed that, with increasing depth of the phase transition zone, the curves lie higher while maintaining all the characteristics of their course. With an increase in the thickness of the dry layer, the hydraulic resistance of the porous structure increases. At the same time, there is an increase in the pressure inside the porous material and of the temperature of moisture evaporation. With an increase in the porosity of the sand, its thermal resistance increases, since the effective coefficient of thermal conductivity of the dry layer decreases. At an identical thickness of the dry layer, an increase in the particle size increases the heat flux through the porous medium and, consequently, increases the consumption of the cooling agent.
